

Python If-Else Practice: Questions & Answers

Compiled from the uploaded question list and your solved ifelse.py program file.

Q1. WAP to check whether a number is positive or negative. If Positive print positive message or else print Negative Number.

```
num=eval(input('Enter the number : '))
if num>0:
    print(f"The given number '{num}' is positive.")
else:
    print(f"The given number '{num}' is negative.")
```

Q2. WAP to check whether a number is even or odd. If even, print message an even or else print message as odd.

```
num=eval(input('Enter the number : '))
if num%2==0:
    print(f"The given number '{num}' is even.")
else:
    print(f"The given number '{num}' is odd.")
```

Q3. Write a program to check whether a given number is greater than 10 or not. if it is greater than 10 print message as greater or else print that number with not a greater than.

```
num=eval(input('Enter the number : '))
if num>10:
    print(f"The given number '{num}' is greater than 10.")
else:
    print(f"The given number '{num}' is not greater than 10.")
```

Q4. WAP to check whether the given two input numbers are divisible by 3 and 5. If it is divisible, print "Good Morning", if it is not divisible print "Good Evening".

```
num1=eval(input('Enter the number1 : '))
num2=eval(input('Enter the number2 : '))
if num1%3==0 and num2%5==0:
    print("Good Morning")
else:
    print("Good Evening")
```

Q5. WAP to accept two integers and check whether those two values are equal or not. If equal, multiply to value or else to display the quotation value.

```
num1=eval(input('Enter the number1 : '))
num2=eval(input('Enter the number2 : '))
if num1==num2:
    print(num1*num2)
else:
    print(' quotation of number =',num1/num2)
```

Q6. WAP to find the largest of two numbers.

```
num1=eval(input('Enter the number1 : '))
num2=eval(input('Enter the number2 : '))
if num1>num2:
    print(f'The number "{num1}" is larger than "{num2}"')
else:
    print(f'The number "{num2}" is larger than "{num1}"')
```

Q7. WAP to check whether the input number is greater than 10 or not if it is greater than 10 print messages as greater with number. if it is not a greater than 10 print that number.

No separate solution was found for this one in your file.

Q8. WAP to the given number integer, if n is greater than 21, print the absolute difference between n and 21 otherwise print twice the absolute difference.

```
num=eval(input('Enter the number : '))
if num>21:
    print(num-21)
else:
    print((num-21)*2)
```

Q9. WAP to find the smallest of two numbers.

```
num1=eval(input('Enter the number1 : '))
num2=eval(input('Enter the number2 : '))
if num1<num2:
    print(f'The number "{num1}" is smallest ')
else:
    print(f'The number "{num2}" is smallesr ')
```

Q10. WAP to check whether the given number is even or odd. If it is even then make it as an add number, if it is an odd number then make it as even number.

No separate solution was found for this one in your file.

Q11. WAP to check whether the given number is divisible by 3 or not if yes, print the number or else print the cube of the numbers.

```
num=eval(input('Enter the number : '))
if num%3==0:
    print(num)
else:
    print(num**3)
```

Q12. WAP to check whether the given input is divisible by 3 and 5. If yes print the actual number or else print string of that number.

```
num=eval(input('Enter the number : '))
if num%3==0 and num%5==0:
    print(num)
else:
    print(str(num))
    print(type(str(num)))
```

Q13. WAP to check whether the given number lies between 1 to 19, if it is true square that number or else false cube that number and display the number.

```
num = eval(input('Enter the number: '))
if 1 <= num <= 19:
    print(f'The square of {num} is ', num ** 2)
else:
    print(f'The cube of {num} is {num ** 3}.')
```

Q14. WAP to check whether the student has passed or failed. If the student got more than 40 marks, print 'PASS' along with those marks, if it is not printed 'FAIL' along with those marks.

```
marks=eval(input('Enter the marks : '))
if marks>=40:
    print(f'PASS with {marks} marks')
else:
    print(f'FAIL with by {40-marks} marks')
```

Q15. WAP to check whether a given value is even and in range of 47 to 58 and not in 0 or odd. if condition is True, to perform display the ascii character. or else to perform floor division with 5 and display it.

```
num = eval(input('Enter the number: '))
if num%2==0 and 47<=num<=58 :
    print(chr(num))
else:
    print(num//5)
```

Q16. WAP to check whether a given value is less than 125 and in between 47 to 125 or not. if condition is True, to perform store the given value as key and value as a character into the dict or else to append the value in list and display it.

```
a={}
b=[]
value = eval(input('Enter the value: '))
if value<125 and 47<=value<=125:
    a.update({value:(chr(value))})
    print(a)
else:
    b.append(value)
    print(b)
```

Q17. WAP to check whether a given character is in the alphabet or not. if alphabet, display the alphabet with character or else display the not alphabet with character.

```
char=eval(input('Enter the character : '))
if char.isalpha():
    print(f'Alphabet with character: {char}')
else:
    print('Not alphabet with character :{char}')
```

Q18. WAP to check whether a given character is uppercase or other character. if uppercase, display the uppercase with character or else display the other character with character.

```
char=eval(input('Enter the character : '))
if char.isupper():
    print(f'Uppercase with character: {char}')
else:
    print(f'Other character with character: {char}')
```

Q19. WAP to check whether a given character is lowercase or other character. if lowercase, display the lowercase with character or else display the other character with character.

```
char=eval(input('Enter the character : '))
if char.islower():
    print(f'Lowercase with character: {char}')
else:
    print(f'Other character with character: {char}')
```

Q20. WAP to check whether a given character is uppercase or other character. if uppercase, convert to lowercase .or else display the ascii number.

```
char=eval(input('Enter the character : '))
if char.isupper():
    print(f'Lowercase character  :',char.lower())
else:
    print(f'character with ASCII: {ord(char)}')
```

Q21. WAP to check whether the given character is in lowercase or uppercase. If it is in lowercase, convert it into uppercase, or else it is in uppercase and convert it into lowercase. Display the value.

```
char=eval(input('Enter the character : '))
if char.islower():
    print(f' character in upper  :',char.upper())
else:
    print(f'character in lower : ',char.lower())
```

Q22. WAP to check whether the given string of the first character is a special symbol or not. If a special symbol, to extract and display the middle character or else to reverse the string and display the half of the string.

```
string=eval(input('Enter the string : '))
if string[0] in '@#$$%^&*?|}{^@!~':
    print(string[len(string)//2])
else:
    a=string[::-1]
    print(a[:len(a)//2])
```

Q23. WAP to check whether the input character is a vowel or not. If it is vowel print 'VOWEL' along with that character, if it is not just print 'CONSONANT'.

```
string=eval(input('Enter the character: '))
if string in 'aeiouAEIOU':
    print(f'The given String contains vowels is "{string}" ')
else:
    print(f'The given String "{string}" is consonant ')
```

Q24. WAP to check whether a given character is a vowel or consonant. if vowel, to print the next character of a given character or else print previous characters.

```
string=eval(input('Enter the character: '))
if string in 'aeiouAEIOU':
    print(f'The given String contains vowels is "{string}" and next character is ',chr(ord(string) + 1))
else:
    print(f'The given String "{string}" is consonant and previous character is ',chr(ord(string) - 1))
```

Q25. WAP to check whether a given string of first character is alphabet or not if the alphabet prints, reverse the string or else print the middle character.

No solution was written for this one in your file.

Q26. WAP to check whether the given input character is uppercase or lowercase. If the input character is upper case convert into lower case and vice versa.

```
char=eval(input('Enter the character : '))
if char.islower():
    print(f' character in upper  :',char.upper())
else:
    print(f'character in lower : ',char.lower())
```

Q27. WAP to check whether a given string is less than 3 characters, to print the entire string otherwise to print after third positions to the remaining string.

```
string=eval(input('Enter the string: '))
if len(string)<=3:
    print(string)
else:
    print(string[3:])
```

Q28. WAP to check whether a given length of the string is even or not. if even, to append the new string called "bye" or else print the first and last characters.

```
s=eval(input('Enter the string: '))
if len(s)%2==0:
    print(s+ ' '+'bye')
else:
    print( f'The first character is "{s[0]}" and the last character is "{s[-1]}"')
```

Q29. WAP to check whether a given length of the string is odd or not. if odd, to append the new string("Haii") from the starting of the given string, or else to avoid the starting character and ending character of the given string and to display the remaining characters.

```
s=eval(input('Enter the string: '))
if len(s)%2!=0:
    print('Haii'+s)
else:
    print(s[1:-1:])
```

Q30. WAP to check whether the last of the given string is a special character or not, if the special character prints reverse the string except the last character or else to check if the length of the string is odd or not, if odd to extract the middle character to the end of the string.

```
string=eval(input('Enter the string: '))
if string[-1] in '@#!$%^&*(){}':
    print(string[::-1][:-1])
else:
    len(string)%2!=0
    print(string[len(string)//2:] + string[:len(string)//2])
```

Q31. WAP to check whether a given year is a leap year or not. if leap year, print leap year or else not a leap year.

No solution for the leap year program was found in your file.

Q32. WAP to find out the greatest of two numbers and display the greatest number. if the greatest number, display the greatest message with value.

No separate solution was found for this one in your file (it is close to the 'largest of two numbers' program above).

Q33. WAP to check whether the given value is present inside the given collection or not. if value is present, display the value is available or else the value is not present.

```
value=eval(input('Enter the value :'))
if value in 'gjhkdkjh23849':
    print('value is available ')
else:
    print('value is not present.')
```

Q34. WAP whether a given string, if string length is more than 2, then it displays a new string with the first and last characters switched, otherwise the display the 3 copies of given string.

```
s=eval(input('Enter the string: '))
if len(s)>2:
    print(s[-1]+s[1:-1:1]+s[0])
else:
    print(s*3)
```

Q35. WAP to check whether a given value is a list and first and last values should be integer if condition is satisfied first value is True division by 3 and perform the bitwise not for last value and those result values are stored in same positions in given list or else, to perform length of the collection power by 2 and display value.

```
a=eval(input('Enter the list'))
if isinstance(a,list) and isinstance(a[-1],int) and isinstance(a[0],int):
    a[0]=a[0]/3
    a[-1]=~a[-1]    #n=-(n+1)
    print(a)
else:
    print(len(a)**2)
```

Q36. WAP to check whether a given value is a string or not and length of the value should be more than 7, if condition is satisfied to append the new string in the middle of the given string or else to perform the replications with 3 and display the result.

```
d='Morningclass'
e='777'
if type(d) and len(d)>7:
    mid=(len(d))//2
    data =d[:mid:]+e+d[mid::]
    print(data)
else:
    print(d*3)
```

Q37. WAP to check if the given string of first and second character should be sequence or not. if the sequence prints the first, second and last two characters, or else the first half string is reversed and the remaining half string should be normal and display it.

```
x=eval(input('Enter the data:'))
low=0
high=len(x)-1
if (ord(x[0]) +1==ord(x[1])):
    print("first",x[0])
    print("second",x[1])
    print("last two",x[-2:])
else:
    mid=(low+high)//2
    print(mid)
    data=x[0:mid+1][::-1]+x[mid+1:]
    print(data)
```

Q38. WAP to check whether a given value is present inside the collection or not. If present, print the value or else print value is not found.

No separate solution was found for this one in your file (it is close to the 'value present in collection' program above).

Q39. WAP to check whether a given key is present in the dict or not. if key is present: display the value or else add key and new value inside the dict.

```
a={3:'df',4:'rrewe',5:'dft'}
d=eval(input('Enter the key : '))
if d in a :
    print(a[d])
else:
    a[7]='cat'
    print(a)
```

Q40. WAP to check whether a given collection is set or not. if set, append the new value, or else eliminate the duplicate values in collection. final results should be set type.

```
a=eval(input('Enter the data'))
if type(a)==set:
    a.add('GHEE')
    print(a)
else:
    print(set(a))
```

Q41. WAP to read the age of a candidate and determine whether it is eligible for his/her own vote or not. if eligible print age and eligible messages or else print not eligible.

```
age=eval(input('Enter the age : '))
if age>=18 :
    print(f'You age is "{age}" then you are eligible for vote')
else:
    print('Not eligible')
```

Q42. WAP to check whether a given value is even and in between 47 to 58 and not in 0 or odd. if condition is True, to perform display the ascii character or else to perform floor division with 5 and display it.

```
value=eval(input('Enter the value : '))
if value%2==0 and 65<=value<=90 :
    print(chr(value))
else:
    print(value//5)
```

Q43. WAP to check whether the given string is palindrome or not if it is a palindrome string palindrome along with the string if it is not a palindrome print not palindrome

```
string=eval(input('Enter the string :'))
if string==string[::-1]:
    print(f'The given "{string}" is palindrome and output is"{string[::-1]}".')
else:
    print('The given string is not palindrome.')
```

Q44. WAP to check whether a given number is palindrome or not. If palindrome, display the given value as a palindrome or else not a palindrome.

```
num=eval(input('Enter the number :'))
if num==num%10:
    print(f'The given "{num}" is palindrome and output is"{num[::-1]}".')
else:
    print('The given string is not palindrome.')
```

Q45. WAP to check length of both string collections are equal or not. if both are equal print the concat the two strings and display, or else if any one of the collection not equal print both the collections with lengths

```
string1=eval(input('Enter the string 1:'))
string2=eval(input('Enter the string 2:'))
if string1==string2:
    print(string1+string2)
else:
    print(f'{string1} has lenght',len(string1))
    print(f'{string2} has lenght',len(string2))
```

Q46. WAP to check whether both given values point to the same memory location or not. if it is true print the middle item of the second collection, or else if it is false print the first item and last item of the first collection along with the memory address.

```
value1=eval(input('Enter the value1:'))
value2=eval(input('Enter the value2:'))
if id(value1)==id(value2):
    mid=(len(value2)-1)//2
    print(value1[mid])
else:
    print(f' The first item {value1[0]} and memory address is {id(value1[0])}')
    print(f' last item {value1[-1]} and memory address is {id(value1[-1])} ' )
```

Q47. WAP to check whether a given string collection is more than ten, and the first + last character of the ascii values should be divisible by 5, if condition is satisfied print first, middle, last characters ASCII values or else print the string three times.

```
s=eval(input('Enter the string:'))

if len(s)>10 and (ord(s[0])+ord(s[-1]))%5==0:
    print('first character : ',ord(s[0]))
    print('middle character :',ord(s[(len(s)-1)//2]))
    print('last character :',ord(s[-1]))
else:
    print(s*3)
```

Q48. WAP to check whether the middle of the item present in the list is string data type or not if it is string print that list or else if it is not string then print that middle item.

```
L=eval(input('Enter the list:'))
mid=(len(L)-1)//2      #position of mid
if type(L[mid])==str:   #for value -->vn[mid]
    print(L)
else:
    print(L[mid])
```

Q49. WAP *Given a string, return a new string where the first and last characters have been exchanged.*

Only the question was written in your file for this one - no code was given.

Q50. Write a program to find out such numbers which are divisible by 7 but are not a multiple of 5. Both the conditional is satisfied and print actual value. if one condition is not satisfied actual number is multiply by 4 and print result

```
num=eval(input('Enter the number: '))
if num%7==0 and num%5!=0:
    print('Actual value is :',num)
else:
    print(num*4)
```

Q51. WAP to check whether two values are pointing to the same memory address or not. If the same memory displays the address or else displays the two values addresses.

```
v1=eval(input('Enter the value1:'))
v2=eval(input('Enter the value2:'))
if id(v1)==id(v2):
    print(id(v1))
else:
    print('memory address of value 1',id(v1))
    print('memory address of value 2',id(v2))
```

Q52. WAP to check whether a given input character is a special symbol or not if it is a special symbol then print that character three times and tell print that character 5 times.

```
char=eval(input('Enter the character:'))
if not char.isalnum():
    print(char*3)
else:
    print(char*5)
```

Q53. WAP to check length of both string collections equal or not if it is equal print the connection of any one of the collections if it is not equal print both the collection.

```
string1=eval(input('Enter the string 1:'))
string2=eval(input('Enter the string 2:'))
if len(string1)==len(string2):
    print(string1+string2)
else:
    print(' string 1 : ',string1)
    print(' string 2 : ',string2)
```

Q54. WAP To check whether both input variables point to the same memory location or not if it is true print the last item of the second collection, if it is false print the first item of the first collection along with the memory address.

```
s1=eval(input('Enter the variable1:'))
s2=eval(input('Enter the variable 2:'))
if id(s1)==id(s2):
    print(f'The last item of the second collection is "{s2[-1]}".')
else:
    print(f'first item of the first collection is {s1[0]} and memory address is {id(s1[0])}')
```

Q55. WAP to print the string collection five times when the length of the string collection should be more than 3 and the middle character of the string should be vowel and the first character ASCII value should be even, to print the previous character of middle character, or else if ASCII value is odd then print the string three times as print that string.

```
string=eval(input('Enter the string :'))
mid=(len(string)-1)//2
if len(string)>3 and string[mid] in 'aeiouAEIUO' :
    if ord(string[0])%2==0 :
        print(chr(ord(string[mid])-1))
        print(string*5)
else:
    print(string*3)
```

Q56. Ravi would like to buy a new cello or red pen. The cost of the pen should be 10. If the pen is available in the shop, he will buy the pen. If it is not there he will come out of the shop.

```
pen_available=eval(input('Enter yes/no : '))
pen_price=eval(input('enter the amount : '))
if pen_available=='yes' and pen_price==10:
    print('Ravi will but a pen ')
else:
    print('Ravi will come out of the shop ')
```

Q57. WAP to perform addition and subtraction operation by using list collection if the first and middle data items number are even performing addition operation, or else performing subtraction.

```
a=[10, 20, 30, 40, 50, 60, 70]
low=0
high=len(a)-1
first_element=a[low]
print(first_element)
mid_element=(low+high)//2
print(mid_element)
print(a[mid_element])
if first_element%2==0 and a[mid_element]%2==0 :
    print(first_element+a[mid_element])
else:
    print(first_element-a[mid_element])
```

Q58. WAP to check whether the first item of these two lists is either integer or not. If it is an integer, concatenate these two lists or else print the memory address of these two lists.

```
list1=eval(input ('Enter the list1 : '))
list2=eval(input ('Enter the list2 : '))
if isinstance(list1[0],int) and isinstance(list2[0],int):
    print(list1+list2)
else:
    print(id(list1))
    print(id(list2))
```

Additional Practice Set (found separately in your file)

These 18 questions and answers were also solved in your ifelse.py but don't appear in the uploaded question list, so they're kept as a separate set.

Q1. wap to check the given number is even or odd (take user input)

```
num=eval(input('Enter the number : '))
if num%2==0:
    print(f'The given number "{num}" is even.')
else:
    print(f'The given number "{num}" is odd.')
```

Q2. wap to check whether the male and female are eligible for wedding (take user input)

```
male=eval(input('Enter the age of male : '))
female=eval(input('Enter the age of female : '))
if male>=21 and female>=18:
    print(f'The male of age {male} and female of age {female} are eligible for wedding .')
else:
    print(f'The male of age {male} and female of age {female} are not eligible for wedding .')
```

Q3. wap to return uppercase if the char is lower,else return same char (by taking user input)

```
char=eval(input('Enter the character : '))
if char.islower():
    print('character in uppercase=',char.upper())
else:
    print('char')
```

Q4. wap to return lower case if the upper ,else return same char (by taking user input)

```
char=eval(input('Enter the character : '))
if char.isupper():
    print('character in lowercase=',char.lower())
else:
    print('char')
```

Q5. wap to find greater value among the two number n1=34 n2=54

```
num1=eval(input('Enter the number 1 : '))
num2=eval(input('Enter the number 2 : '))
if num1>num2:
    print(f'The "{num1}" is greater than "{num2}" .')
else:
    print(f'The "{num2}" is greater than "{num1}" .')
```

Q6. wap to check if the given number is even or not,if it is not even add+1 and make it even (take user input)

```
num=eval(input('Enter the number : '))
if num%2!=0:
    print(f'The number "{num}" is odd and its converted into even is ',num+1)
else:
    print('The number is even .')
```

Q7. wap to check whether the first character in the given string is starting with uppercase or Not if it is not Then capitalize it s="python".

```
char=eval(input('Enter the character : '))
if char[0]==char.isupper():
    print('The given string first character is in uppercase.')
else:
    print(char.capitalize())
```

Q8. wap to check if the given number is even ,if it is even reduce it to its Half else make exponent (take user input)

```
num=eval(input('Enter the number : '))
if num%2==0:
    print(f'The given number "{num}" is even and its half is ',num/2)
else:
    print(f'The given number "{num}" is not even and its exponent is ',num**2)
```

Q9. *wap to check number should be divisible by 3 and 7 (take user input)*

No solution was written for this one in your file.

Q10. wap if the length of string is even then reverse else convert into upper case (take user input)

```
string=eval(input('Enter the string : '))
if len(string)%2==0:
    print('The length of string is even.',string[::-1])
else:
    print("The length of string is not even and it is in uppercase =",string.upper())
```

Q11. wap to check a number is +ve/-ve number (take user input)

```
num=eval(input('Enter the number : '))
if num>0:
    print('The number is positive.')
else:
    print('The number is negative.')
```

Q12. wap to check a data is individual or collection data type or not (take user input)

```
data=eval(input('Enter the data : '))
if type(data) in (str,tuple,list,set,dict):
    print('The given data is collection data type.')
else:
    print('The given data is individual data type .')
```

Q13. wap to check whether the specified character is present in the given string

```
c='A'
char=eval(input('Enter the String : '))
if c in char:
    print('The specified character is present in string.')
else:
    print('The specified character is not present in string.')
```

Q14. wap to check the length of dictionary is even or Not if even print as it is or else add a item and make it even

```
D={"a":"apple", "b":"ball", "c":"cat"}
if len(D)%2==0:
    print(D)
else:
    D.update({"d":"5"})
    print(D)
```

Q15. wap to check the given number is greater than 5,if it is greater convert that number into negative number else print the same number

```
num=eval(input('Enter the number : '))
if num>5:
    print(-(num))
else:
    print(num)
```

Q16. wap to check the given number is smaller than 10 ,if it is smaller find the exponent of it else print the number as it is

```
num=eval(input('Enter the number : '))
if num<10:
    print(f"The given number '{num}' is smaller than 10 and its exponent is ",num**2)
else:
    print(f"The given number '{num}' is greater than 10 then ",num)
```

Q17. wap to check the given number is odd, if it is odd divide it by 2 and print reminder and quotient else print it is even (take user input)

```
num=eval(input('Enter the number : '))
if num%2==1:
    num/2
    print("reminder",num%2)
    print("quotient",num//2)
else:
    print("It is even.")
```

Q18. wap to check if the given character is alphabet or Not ,if it is alphabet, create a replica of it 2 times. (take user input)

```
char=eval(input('Enter the Character : '))
if char.isalpha():
    print(char*2)
else:
    print(char)
```
